

Cluster Toplogy Matters!

Big Data Analysis with Scala and Spark

Heather Miller

Example 1: A Simple println

Let's start with an example. Assume we have an RDD populated with Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
people.foreach(println)
```

What happens?

Example 2: A Simple take

What about here? Assume we have an RDD populated with the same definition of Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
val first10 = people.take(10)
```

Where will the Array[Person] representing first10 end up?

Back to Example 1: A Simple println

Let's start with an example. Assume we have an RDD populated with Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
people.foreach(println)
```

Back to Example 1: A Simple println

Let's start with an example. Assume we have an RDD populated with Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
people.foreach(println)
```

On the driver: Nothing. Why?

Back to Example 1: A Simple println

Let's start with an example. Assume we have an RDD populated with Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
people.foreach(println)
```

On the driver: Nothing. Why?

Recall that foreach is an action, with return type Unit. Therefore, it is eagerly executed on the executors, not the driver. Therefore, any calls to println are happening on the stdout of worker nodes and are thus not visible in the stdout of the driver node.

Back to Example 2: A Simple take

What about here? Assume we have an RDD populated with the same definition of Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
val first10 = people.take(10)
```

Where will the Array[Person] representing first10 end up?

Back to Example 2: A Simple take

What about here? Assume we have an RDD populated with the same definition of Person objects:

```
case class Person(name: String, age: Int)
```

What does the following code snippet do?

```
val people: RDD[Person] = ...
val first10 = people.take(10)
```

Where will the Array[Person] representing first10 end up?

The driver program.

In general, executing an action involves communication between worker nodes and the node running the driver program.

Cluster Toplogy Matters!

Moral of the story:

To make effective use of RDDs, you have to understand a little bit about how Spark works under the hood.

Due an API which is mixed eager/lazy, it's not always immediately obvious upon first glance on what part of the cluster a line of code might run on. It's on you to know where your code is executing!

Even though RDDs look like regular Scala collections upon first glance, unlike collections, RDDs require you to have a good grasp of the underlying infrastructure they are running on.
